Take-Home Technical: Algosoup

Time limit: 1 hour

Build and deploy a real web product that you think people would use and pay for.

Here are some examples:

- AI radiology worklist prioritizer for hospitals
- Restaurant inventory and waste prediction system
- AI copilot for estate agents to manage buyers and listings
- Warehouse picking optimizer with AI-generated routes
- Private equity deal screening workspace
- AI fleet management dashboard for logistics companies
- Clinical trial participant matching platform
- Fraud investigation workspace for fintech companies
- Hotel operations dashboard that predicts staffing and occupancy needs
- Field service dispatch board that assigns technicians to jobs by skill, location and SLA
- Clinic waitlist that automatically offers cancelled appointment slots to the next patient
- Equipment rental system with live availability, deposits and damage check-in
- Multi-site stock transfer planner that rebalances inventory before stockouts
- Subcontractor payment tracker with milestones, retentions and approvals
- Property maintenance ticketing between tenants, landlords and contractors
- Freight load board that matches small hauliers to return-trip loads

You can use one of these examples, but we'd prefer if you came up with your own idea.

Simple LLM wrappers will be rejected. A plain UI with a text box or file upload that passes the input to an LLM and shows the response is not enough, however polished. We are looking for good product instinct: a proper data model, workflows, state, integrations, or logic beyond prompting a model.

Required submission

Please send:

1. **GitHub repo URL**
2. **Live deployed app URL**
3. **Coding agent logs**
    - For Claude Code, use `/export`.
    - For other agents, send the equivalent full transcript/logs.
    - Do not clean, rewrite, or selectively edit the logs.

Evaluation criteria

We are looking for evidence that you can use AI tools to ship real software quickly.

We will evaluate:

- **Product judgment -** Is the chosen workflow useful? Did you make good scope decisions for 1 hour? Is the product coherent?
- **Engineering judgment -** Is the code simple and maintainable? Is the data model sensible? Are edge cases handled reasonably? Is the app deployable and easy to understand?
- **AI-native workflow -** Did you use the coding agent thoughtfully? Did you provide good context? Did you review, test, and steer the agent? Did you avoid blindly accepting bad output?
- **Execution -** Does the app work live? Is the core flow complete? Are there obvious bugs? Did you finish within the stated time?

Constraints

- Spend no more than **1 hour**.
- You may use any AI/model provider.
- You may use starter templates, UI libraries, and hosted services.
- Do not hide or edit your coding agent logs.
- Simple LLM-wrapper builds will be rejected (see above).
